help public health planners allocate resources more effectively by identifying, high-risk groups, hesitant groups and regions or demographics with lower expected uptake

4.Focus on recall when evaluating interventions. Because missing people who are unlikely to vaccinate can weaken intervention efforts, stakeholders should pay close attention to recall when choosing the best predictive model.

Conclusion

This project developed a machine learning model to predict whether an individual received the *H1N1 vaccine* using survey data from the National 2009 H1N1 Flu Survey.The model helps public health stakeholders identify the factors that influence vaccine uptake and predict which groups are less likely to vaccinate. These insights can support targeted awareness campaigns, healthcare planning, and better vaccine distribution strategies.
